DATATRON DIGITAL COMPUTER MODEL 204

## GENERAL

Electronic data processing systems have five components - input, storage (working and auxiliary), arithmetic, control, and output. This handbook describes the characteristics and explains the use of the DATATRON Digital Computer Model 204 (called the DATATRON). This unit, which consists of the Computer Cabinet, the Power Control, and the Motor-Generator (Figure 1), contains the working storage, arithmetic, and control components of a complete system. A Stabiline Voltage Regulator (not shown in Figure 1) is also included in the basic DATATRON.

## DATATRON ELECTRONIC DATA PROCESSING SYSTEMS

The DATATRON is a general purpose, internally programmed, decimal, electronic computer with magnetic drum storage. It is the heart, or central controlling and processing unit, of an electronic data processing system which accomplishes the functions of:

1. Accepting data directly from punched cards, punched tape, magnetic tape, keyboard-employing input units singly or in multiple.
2. Selecting from magnetic tape files the historical or reference records necessary to process data.
3. Processing data - comparing, computing, analyzing, sorting, classifying as required -in obedience to a series of commands (instructions) which have previously been stored in the system (stored program).
4. Bringing up to date the historical or reference records maintained on magnetic tape, and returning the up-dated records to magnetic tape.
5. Transmitting required information directly into punched cards, punched tape, magnetic tape, printed documents, visual indications - employing output units singly or in multiple.

As a result of its ability to control data processing systems of wide scope, and because of its economical and reliable operation, the DATATRON has been applied effectively to a wide range of commercial, manufacturing, scientific and engineering problems.

In speed of computer operation, the DATATRON is classed below the very large-scale electronic data processors - and considerably above card-programmed computers, other externally programmed computers, and the small, stored program computers.

In capacity and data processing capability, the DATATRON (as the central unit in a system) approaches large-scale systems in power and ability to produce an effective and economical flow of work.

## COMPONENTS OF THE DATATRON

The Computer Cabinet contains the arithmetic and control units (see Figure 1). The center section contains the magnetic drum working storage and the Control Panel. Switches, indicators, and displays required by the operator are mounted on this panel.

The Motor-Generator converts electric power as furnished to the installation into three stable levels of direct current voltage. This unit may be installed at some distance from the Computer Cabinet, or it may be installed, if properly soundproofed, in the immediate vicinity of the other components of the DATATRON.

The Power Control converts the output of the MotorGenerator into the eight highly stable levels of direct current voltage required by the DATATRON. It contains controls and meters for monitoring these voltages (a maintenance function), and the controls for starting and shutting down the DATATRON.
The Voltage Regulator refines alternating current voltage as supplied to the installation, furnishing a regulated power supply to the vacuum tube filaments. The output of the Voltage Regulator is routed through the Power Control on its way to the Computer Cabinet.

## OPERATING CHARACTERISTICS OF THE DATATRON

## HOW INFORMATION IS REPRESENTED IN THE DATATRON

Information is represented in the DATATRON as fixed length numbers, each of which contains ten decimal digits. Each ten digit number is preceded by an additional digit (Figure 2) which

- represents the algebraic sign of the number, or
- is sometimes used to control machine operation, or
- is an arbitrary zero having no special significance.

Each of these eleven digit units of information, called a word, may represent numerical data, alphabetic data, alphanumeric data, or a command which the DATATRON is to obey. For example:

04259644955 represents the number +4259644955
04259644955 represents the noun BRUIN
04259644955 represents the command "Clear the A Register. Add the contents of storage cell 4955 ."

## 04259864955 represents Part Number B R 6 I N

The position of the word 04259644955 in storage, in relation to the commands (stored program) which the DATATRON is to obey, determines which of the three possible interpretations illustrated above will be applied to the word.

Figure 2
The eleven digit word is treated as a unit by the DATATRON. It is stored as a unit, and it is manipulated as a unit. However, if it is necessary to break up a word into smaller units of information, or to combine words into longer records, this can be done by placing the proper series of commands in the DATATRON.

## HOW INFORMATION IS STORED IN THE DATATRON

Over 4000 words of information are stored in the DATATRON on the surface of a large-capacity magnetic drum which revolves at 3570 revolutions per minute This unusual storage capacity makes possible

- adequate reference to data,
- adequate facility for classification of data,
- convenient use of long programs,
- convenient insertion of temporary programs for "spot" analysis,
- improved internal sorting techniques, and
- a reduction, in many cases, in the number of times the same data must be fed through the central data processor to secure the desired results.

Once placed on the drum, information is retained (whether or not the power is turned on) until it is "erased" by writing new information on the drum over the old information.

Only the digits zero and one are represented on the surface of the magnetic drum - and this representation is made by magnetizing a small spot on the drum for each digit. All zero spots are magnetized in the same direction of polarity, and all one spots are magnetized alike in the opposite direction. Four such spots (called bits of information or binary digits) are used to represent one decimal digit. In this scheme of representation (binary-coded decimal), one bit of information is assigned the value 1 , the second bit is assigned the value 2, the third bit is assigned the value 4, and the fourth bit is assigned the value 8. Decimal digits are represented according to the following table:

|  | $\mathbf{0}$ | $\mathbf{1}$ | $\mathbf{2}$ | $\mathbf{3}$ | $\mathbf{4}$ | $\mathbf{5}$ | $\mathbf{6}$ | $\mathbf{7}$ | $\mathbf{8}$ | $\mathbf{9}$ |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- |
| $\mathbf{8}$ Bit | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 1 | 1 |
| $\mathbf{4}$ Bit | 0 | 0 | 0 | 0 | 1 | 1 | 1 | 1 | 0 | 0 |
| $\mathbf{2}$ Bit | 0 | 0 | 1 | 1 | 0 | 0 | 1 | 1 | 0 | 0 |
| $\mathbf{1}$ Bit | 0 | 1 | 0 | 1 | 0 | 1 | 0 | 1 | 0 | 1 |

Write heads and read heads are mounted on the magnetic drum casing (Figure 3). As the drum cylinder revolves inside the casing, the surface of the drum passes these heads. The function of each write head is to place

Figure 3 Magnetic Drum Assembly
information on the surface of the drum by magnetizing four spots at a time according to the code tabulated above. The function of each read head is to interpret the pattern of magnetic spots on the surface of the drum, four bits of information at a time, thus making the information available for use.

## LOCATION OF INFORMATION ON THE MAGNETIC DRUM

A space on the drum large enough to write the contents of exactly one word is called a storage cell. Storage cells are arranged in bands which extend around the circumference of the magnetic drum. Each band consists of four tracks of magnetized spots (Figure 4), making possible the use of the binary-coded decimal scheme of representing digits. Four zeros, one in each of the tracks, separate each word from its adjoining words. Associated with each band is a read head and a write head, or a combination read-write head.

Figure 4 Information Stored on a Drum
Each storage cell on the magnetic drum has its own address, a four digit number which identifies the cell and specifies its location. The top twenty bands on the magnetic drum (Figure 5) each contain 200 words, a total of 4000 storage cells being located in the portion of the magnetic drum called main storage. The addresses of these cells are the numbers 0000 through 3999. The bottom four bands on the drum each contain exactly twenty different words. These are the four quick access loops which make up the DATATRON's high speed storage or loop storage. The addresses of the cells in the loops are the numbers 4000 through 7999. However, since each loop contains twenty words, cell 4020 contains the same word as cell 4000 , cell 5569 contains the same word as cell 5009 , cell 6738 contains the same word as cell 6018 , etc. The larger address numbers are sometimes used to achieve desirable programming effects.

## OPERATION OF QUICK ACCESS STORAGE LOOPS

Each main storage band has associated with it one combination read-write head (Figure 6). A word stored in a main storage cell passes the read-write head only once in every revolution of the magnetic drum. A word stored in a main storage cell is available for use, then, once in every revolution of the drum. The access time (or waiting time) for this word can vary from zero to 0.017

Figure 5 Location of Information on Magnetic Drum
seconds ( 17 milliseconds). The average access time for the word is 8.5 milliseconds, the time for a half-revolution of the drum.

Each quick access loop has a separate read head and, twenty words distant from this head along the drum circumference, a separate write head (Figure 7). Since a complete band around the magnetic drum contains 200 words, these two heads are one-tenth of the drum circumference apart.

As each word passes under the read head, it is always immediately rewritten twenty words back along the drum circumference. If a block of twenty words is placed in a quick access loop, this continual process of reading and writing will duplicate the twenty words in ten locations around the drum - in the first revolution of the magnetic drum following the transfer of information into the loop.

A word stored in one of the cells of a quick access loop is available for use once in every one-tenth of a drum revolution, or ten times in every revolution. In effect, the quick access loops supply data and commands at the same rate as if the magnetic drum were revolving at 35,700 revolutions per minute. The access time for a word in a loop can vary from zero to 1.7 milliseconds. The average access time for a word stored in a loop is 0.85 milliseconds.

In most applications, DATATRON commands are transferred from main storage into the quick access loops before the execution of the commands. Similarly, data and intermediate results are normally stored in the quick access loops, or transferred from main storage into the quick access loops.

To accomplish the necessary manipulation of information, block transfer commands are used. These commands move twenty words at a time from main storage to loop, or from loop to main storage, at the rate of 1.7 milliseconds per block of twenty words. Thịs is the amount of time required for twenty words to pass by a read head. The actual transfer of each digit is almost instantaneous.

Words transferred from main storage to a loop remain (in unaltered form) in main storage, facilitating the process of making memo entries in records. Words transferred from a loop to main storage remain (in unaltered form) in the loop.

DATATRON programs are written to maintain a continuous flow of data and commands through the loops. Thus, the DATATRON maintains the high rate of processing associated with optimum (or minimal access) programming, but retains the reliability inherent in a conservative speed of drum revolution.

## ELECTRONIC REGISTERS

On the magnetic drum, each decimal digit is represented by a combination of four magnetized spots, each spot being an indicator of either zero or one. This method of representing information has proven to be extremely reliable.

An electronic circuit, called a flip-flop, can also represent zero or one by being in one of two possible states - either "low" or "high." Several registers, or storage cells with zero access time, use the flip-flop circuit to store information. In these registers, each decimal digit is represented by four flip-flops. Just as in the case of the magnetized spots on the magnetic drum, relative values are assigned to each flip-flop. The first flip-flop is assigned the value 1 , the second flip-flop is assigned the value 2, the third flip-flop is assigned the value 4, and the fourth flip-flop is assigned the value 8. Decimal digits are represented in electronic registers according to the table of combinations used to represent decimal digits on the drum. (Refer to How Information is Stored in the DATATRON.)

Figure 6 Access to Word Stored in Main Storage Band

Figure 7 Access to Word Stored in Quick Access Loop

## ARITHMETIC REGISTERS

Three electronic registers are used to contain numbers involved in computation and data processing (Figure 8).

A Register holds an eleven digit word. This register is an accumulator in which the results of all arithmetic operations appear.

R Register holds ten decimal digits. This register is primarily an extension of the A Register. However, multiplication and division are the only arithmetic operations which affect the R Register.

Figure 8 Arithmetic Registers
D Register holds an eleven digit word which cannot be manipulated by the programmer. The function of this register is to distribute the words passing through it to their proper destinations, routing command words along one path and routing data words along another path.

One of the numbers involved in an arithmetic operation is always in the A Register, or in the combined A Register and R Register. The second number involved is always transferred from the drum into the D Register.

## COMMAND STRUCTURE

A DATATRON command is made up of three parts (Figure 9):
(a) the four digit address - which designates the location of the storage cell referred to during execution of the command;
(b) The two digit order - which designates the specific operation to be performed;
(c) the five control digits - which designate variations in the execution of the command.

Figure 9 Command Structure

## C REGISTER

C Regisfer receives each command from the magnetic drum through the D Register (Figure 10). The function of this register is to start the operation of the control component of the DATATRON.

The C Register is composed of three sub-registers (reading from left to right) :

Order Register holds the two digits which designate the specific operation to be performed.

Address Register holds the four digits which designate the location of the storage cell referred to during execution of the command. The contents of the Order Register and the Address Register, together, are the same as the six right hand digits of the command word as it appears in the D Register and on the magnetic drum.

Control Counter holds the four digits which specify the address of the next command which will be executed - after the completion of the operation specified in the Order Register and the Address Register.

## OPERATION SEQUENCE

In normal, continuous operation, commands are executed in the order in which they are stored on the magnetic drum. Thus, if commands are stored in storage cells 1000 , 1001, and 1002, the command stored in cell 1001 will be executed after the command stored in cell 1000 and the command stored in cell 1002 will be executed after the command stored in cell 1001.

The Control Counter counts up 1 after each command comes into the C Register so that the next command will be read from the next cell. In the preceding example, when the command stored in cell 1000 is being executed,
the Control Counter will read 1001. When the command stored in cell 1001 is being executed, the Control Counter will read 1002 (Figure 10).

To change this normal method of sequential operation, change of control commands are used. These commands may be used to alter the sequence of command execution arbitrarily - in which case they are unconditional changes of control. A similar series of commands may be used to alter the sequence of command execution only in response to the presence of a machine condition (see Overflow, below). These conditional changes of control are used for decision-making or branching.

Instead of allowing the Control Counter to count up 1 , the change of control commands insert their address digits into the Control Counter, and thus specify the next command to be executed.

## OPERATION CYCLE

As has been noted, the D Register sends command words along one path, and data words along another.

In the fetch phase of the operation cycle (Figure 11), the command word located in the storage cell specified in the Control Counter is brought from the magnetic drum, through the D Register, through the Adder, to the C Register.

In the execute phase of the operation cycle (Figure 12), the data word specified in the command just fetched is brought from the magnetic drum, through the D Register, through the Adder (where an arithmetic operation takes place) to the A Register.

During DATATRON operation, the fetch phase and the execute phase alternate as the operation cycle repeats.

 AND ADDRESS REGISTERS AND ADVANCE CONTROL COUNTER 1

PERFORM "64" COMMAND -
CLEAR THE A REGISTER.
ADD THE CONTENTS OF CELL 3236

Figure 10 Action of Control Counter

Figure 11 Operation Cycle

## B REGISTER

The B Register holds any four decimal digits from 0000 to 9999 . These digits can be added to the address digits of a command word as the command goes through the Adder to the C Register (Figure 13).

The addition of the contents of the B Register to a command (command modification) is signalled by the first control digit of the command word, when the word reaches the D Register. If the digit is 1 , the contents of the B Register are added. If the control digit of the command word is 0 , the contents of the B Register are not added (see Figure 11).

The contents of the B Register can be increased by one, or decreased by one, during the execution of a series of commands. When the series of commands is repeated many times, the B Register can serve, in this case, as a tallying device.

## DECIMAL POINT

Inside the DATATRON, a decimal point is considered to be fixed at the left of each ten digit word stored on the magnetic drum or in the electronic registers.

The eleventh digit, at the left of the decimal point, represents the algebraic sign of numerical data (zero for plus and one for minus), or (in the case of a command word) is sometimes used to control machine operation, or (in the case of alphabetic or alphanumeric data) is an arbitrary zero having no special significance.

Outside the DATATRON, the decimal point may be located in its proper position (by programming) regardless of its internal position. For example:

| Infernally |  | Externally |
| :---: | :---: | :---: |
| 01621000000 |  | 16.21 |
| 00001621000 |  |  |
| 00000001621 | may be represented as | 16.21 |
|  |  | 16.21 |

When a number in the combined A Register and R Register is shifted left, the shifting command may tally

Figure 12 Operation Cycle

Figure 13 B Register Modification
the number of positions shifted and record this number in a register called the Special Counter. The contents of the Special Counter may later be added to or subtracted from the A Register.

## OVERFLOW

Whenever the execution of a command produces a result which is too large to be inserted in the A Register, an overflow condition is set up in the DATATRON. This is the machine condition which can result in a conditional change of control (previously discussed in the handbook section, Operation Sequence). The presence of the overflow condition is determined as follows:
Indication to DATATRON - Overflow flip-flop is in a "high" state.
Indication to operator - Overflow light is ON .

## EXAMPLE 1

Actual Arithmetic
0.9000000000
$+0.8000000000$
$1.7000000000^{*}$
*Carry produces overflow to the left.

## DATATRON Arithmetic

09000000000
08000000000 0700000 0000**
**Overflow indicates ON. Zero to the left of decimal point position represents plus sign.

EXAMPLE 2
Actual Arithmetic
$0 . 3 0 0 0 0 0 0 0 0 0 \longdiv { 3 . 0 0 0 0 0 0 0 0 0 0 ^ { * } } \begin{array} { r } { 0 . 9 0 0 0 0 0 0 0 0 0 } \end{array}$
*Division of larger number produces overflow to the left.

DATATRON Arithmetic

$$
\begin{gathered}
0 3 0 0 0 0 0 0 0 0 0 \longdiv { 0 9 0 0 0 0 0 0 0 0 0 * * } \\
\text { ** Overflow indicates ON. } \\
\text { Zero to the left of } \\
\text { decimal point position } \\
\text { represents plus sign. }
\end{gathered}
$$

The overflow condition may follow the arithmetic manipulation of the contents of the A Register. Overflow always follows the test for and detection of a difference between the algebraic sign of the A Register and the
sign of a number brought from a storage cell for comparison.

When the possible appearance of an overflow is anticipated, a conditional change of control command is inserted in the program to allow the program to branch (take one of two possible alternate paths). When an unanticipated overflow occurs (a programming error) the DATATRON stops.

## CHECKING FACILITIES

The DATATRON automatically stops upon the appearance of an unanticipated overflow (see Overflow).

An alarm light is turned on and computation is stopped by a forbidden combination (binary-coded decimal digits 10 through 15) in the A, B, D, and R Registers, the Address Register, the Control Counter, and the Shift Counter. Inspection of the register contents as indicated on the Control Panel indicates the failure location.

An alarm will stop machine operation if the storage cell counter does not contain 0 at the start of each drum revolution. This check prevents information from being recorded on or read from incorrect locations on the drum.

An audible alarm indicates excessive rise in exhaust air temperature in the computer cabinet and after a preset interval up to 15 minutes, dc voltages will be shut off if the temperature stays at or above a predetermined level.

A very extensive marginal checking system is available to maintenance personnel. This system makes it possible to vary voltages applied to each section of the DATATRON to induce errors caused by marginal components. The use of the marginal checking system greatly simplifies the operation of an effective preventive maintenance system.

Figure 14 Marginal Checking Panel

This section defines the DATATRON commands available to the programmer and illustrates their use. Appendix I of this handbook contains a summary of these commands.

## ARITHMETIC

## Commands for Addition and Subtraction.

Addition and substraction commands affect the A Register, but not the R Register.
The series of commands below illustrates the use of the add and subtract commands, and the effect that each command has on the A Register and the $R$ Register.

Assume that:

1. Storage cell 1000 contains the number 02222222222.
2. Storage cell 1001 contains the number 13333333333.
3. The A Register contains the number 19874531234.
4. The R Register contains the number 0000560000.
5. Insert a 7 on Keyboard for Digit Add.

Stop machine operation. Add the next digit read (from manual keyboard or paper tape reader) to the least significant position of the A Register.

The condition of overflow in AD, ADA SU, SUA is possible and will appear as follows:

| Program |  | A Register | R Register |
| :---: | :---: | :---: | :---: |
|  |  | 19874531234 | 0000560000 |
| *SU | 1000 | 12096753456 | 0000560000 |
| SUA | 1001 | 15430086789 | 0000560000 |
| CADA | 1001 | 03333333333 | 0000560000 |
| ADA | 1001 | 06666666666 | 0000560000 |
| ADA | 1001 | 09999999999 | 0000560000 |
| * ADA | 1001 | 03333333332 | 0000560000 |

Addition and Subtraction commands can be used in: Posting; Accumulating receipts, Debiting and Crediting accounts, and in general, Updating records.

PROBLEM: A store has four sections. Following each day's business the owner wants to know net receipts. Each section reports total receipts and amount of sales commissions.
TO FIND: Net Receipts

ASSUME: Information from sections located in memory cells:

| 1000 | 00000019432 | (Section 1 - Sales) |
| :--- | :--- | :--- |
| 1001 | 00000003886 | (Section 1 - Commissions) |
| 1002 | 00000015203 | (Section 2 - Sales) |
| 1003 | 00000003040 | (Section 2 - Commissions) |
| 1004 | 00000009367 | (Section 3 - Sales) |
| 1005 | 00000001873 | (Section 3 - Commissions) |
| 1006 | 00000010152 | (Section 4 - Sales) |
| 1007 | 00000002030 | (Section 4 - Commissions) |

SOLUTION:

| Location |  | $\begin{array}{r} \text { Control } \\ \hline \text { Digits } \\ \hline \end{array}$ |  | Operation |  | OperandAddres | Remarks |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Main | Loop |  |  | NO | Alphä |  |  |
|  |  |  |  |  |  |  |  |
| 0000 | 0 |  |  |  | CAD | 1000 | A = 0.0000 ol 9432. |
| 0001 | 1 |  |  |  | su | 1001 | $A=0.0000$ or 5546. |
| 0002 | 2 |  |  |  | $A D$ | 1002 | $A=0.0000030749$. |
| 2003 | 3 |  |  |  | su | 1003 | $A=0.0000027709$ |
| 0004 | 4 |  |  |  | $A D$ | 1004 | $A=0.0000037076$. |
| 0005 | 5 |  |  |  | SU | 1005 | $A=0.000003 \quad 5203$. |
| 0006 | 6 |  |  |  | AD | 1006 | $A=0.0000045355$. |
| 2007 | 7 |  |  |  | su | 1007 | $A=0.0030$ at 3325. |

Multiplication and division commands affect both the $\mathbf{A}$ Register and the R Register.
The series of commands below illustrates the use of commands for multiplication and division, and the effect that each command has on the A Register and the R Register.

## 2

Assume that:

1. Storage cell 1000 contains the number 02222222222.

## - MULTIPLICATION <br> M 000 p 60 xxxx

Multiply the contents of xxxx by the contents of the $\mathbf{A}$
Register. Insert the twenty digit product in the A Register and the $R$ Register. The most significant digits are in the A Register.

## MRO

000p 70 xxxx MULTIPLY, ROUND
Multiply the contents of $\mathbf{x x x x}$ by the contents of the $A$ Register. Round the product to ten digits. Clear the $\mathbf{R}$ Register.
During the execution of the Multiply command, the $R$ Register is cleared to permit the insertion of the least significant ten digits of the product.

The A Register will contain the proper algebraic sign of the product.

## DIVISION <br> DIV

DIVIDE
000 p 61 xxxx
Divide the twenty digit contents of the A Register and the $\mathbf{R}$ Register by the contents of $\mathbf{x x x x}$.
(a) If Overflow indicates ON, clear the A Register and the $\mathbf{R}$ Register.
(b) If Overflow indicates OFF, insert the quotient in the A Register, and insert the undivided remainder (if any) in the $\mathbf{R}$ Register.
In division, the divisor must be greater than the portion of the dividend in the $A$ Register. If the dividend is greater than or equal to the divisor, the quotient will exceed the capacity of the A and R Register and an overflow will occur. If the dividend is contained in the $A$ Register, then the $\mathbf{R}$ Register must be cleared before dividing.
2. Storage cell 1001 contains the number 13333333333.
3. The A Register contains the number 09999999999.
4. The R Register contains the number 9999999999.

Example of overflow in division:

| Program |  | A Register | R Register |
| :---: | :---: | :---: | :---: |
|  |  | 09822709243 | 0000000000 |
| CAD | 1001 | 13333333333 | 0000000000 |
| *DIV | 1000 | 00000000000 | 0000000000 |

Multiplication and Division commands can be used in: Determining rates, Payroll extension, Billing, Tax computation, and general engineering computations.
PROBLEM: A store owner wants to take advantage of a close-out sale to purchase 2,250 items at $\$ 10.00$ each. There will be a shipping cost of $\$ 380.00$. There is a $\$ 909.00$ discount if the purchase is made on an 18 month contract at $6.5 \%$ interest. The store owner wants to know what his monthly interest payments will be.

TO FIND: Monthly interest payments.
ASSUME: Information for purchase located in memory cells:

| 1000 | 00002250000 | (Quantity) |
| :--- | :--- | :--- |

## SOLUTION:

## MANIPULATION AND TRANSFER OF INFORMATION

SL

## SHIFT LEFT

000p 1400 mn
Shift the contents of the A Register and the $\mathbf{R}$ Register min places left. The ma digits shifted out of the left end of the A Register re-enter the right end of the R Register in the same order. The sign does not move.

## SR

000 p 1300 nn
Shift the contents of the A Register and the R Register nn places right. The nn digits shifted out of the right end of the $R$ Register are lost, and $n n$ zeros enter the left end of the A Register. The sign does not move. The maximum value for nn is 19.

Overflow can not occur on shifting commands.

## CR

000p 330000
Clear the $R$ Register.

## RO

000p 230000
Round the twenty digit contents of the A Register and the $R$ Register to ten digits. Clear the $R$ Register. STOP
000p 080000
STOP ${ }^{\prime}$
Stop machine operation.
The operation of the DATATRON stops, but no information is lost. Operation is resumed at the next program step when the START button is pressed.

|  |  | Program |  | A Register | R Register |
| :---: | :---: | :---: | :---: | :---: | :---: |
| ST |  |  |  | 07133219821 | 4792014910 |

Manipulation commands are provided in the DATATRON to facilitate the effective use of arithmetic commands during operation.

PROBLEM: A store wants to take advantage of a closeout sale of purchase 2,250 items at $\$ 10.00$ each. There will be a shipping cost of $\$ 380.00$. There is a $\$ 909.00$ discount if the purchase is made on an 18 -month contract at $6.5 \%$ interest. The store owner wants to know what his monthly principal and interest payments will be.

TO FIND: Monthly payments-principal and interest. ASSUME: Information for purchase located in memory cells:

100000000002250 (Quantity)
100100000001000 (Unit Price)
100200000038000 (Shipping Cost)
100300000090900 (Discount)
100400000000065 (Interest Rate)
100500000000018 (Number of Payments)

SOLUTION:

ANSWER: Located in memory cells 1008 (17 monthly payments), and 1009 (last payment).

| ET4 34 BLOCK | Program |  | A Register | R Register |
| :---: | :---: | :---: | :---: | :---: |
| 000p 34 xxxx |  |  | 16214912721 | 2179430198 |

In blocking to a quick access loop, main storage is unchanged and the previous contents of that loop are completely erased.

In blocking from a quick access loop to main storage, 20 words in main storage are erased and 20 new words are written. The quick access loop remains unchanged.
alike.
The contents of 1020-1039, loop 5, and 2680-2699 are alike.
 digit in the A Register remains unchanged if the digit in the corresponding position in $\mathbf{x x x x}$ is one.

| CIRA <br> 000p 01 00mm | , | Program |  | A Register | R Register |
| :---: | :---: | :---: | :---: | :---: | :---: |
| Shift the conten |  |  |  | 16214912721 | 2179430198 |
| places left. Th |  | RA | 0006 | 27211621491 | 2179430198 | A Register re-enter the right end of the A Register in the same order.

| UA <br> 000p | 0000 UNIT ADJUST | Program |  | A Register | R Register |
| :---: | :---: | :---: | :---: | :---: | :---: |
| IncreaseRegister |  |  |  | 16214912721 | 2179430198 |
|  | if the digit in this position is even. | UA | - 0000 | 17214912721 | 2179430198 |
|  |  | UA | 0000 | 17214912721 | 2179430198 |

When the digit is odd, there is no change. The sign of the A Register is immaterial.

The Block transfer commands enable the programmer to place data in the quick access loops and thereby shorten operation time. The manipulation commands presented on the opposite page are excellent for editing and separating parts of a word.
PROBLEM: A warehouse maintains a file of supplies. The data is filed in the following code:
O uuvw wx xyyy
where: $u u$ is the Supplier code
$v$ is the Color code
$w w$ is the Warehouse Classification code
$x x$ is the Assembly code
$y y y$ is the Detail code

It has been determined that the Warehouse Classification code should be revised to contain three digits and that the color code is not necessary. The current files shall be assigned the Warehouse Classification code of lww ( 100 plus the current code number).
TO FIND: Revised file. (Only one file will be revised in the example program below.)

ASSUME: Example file for revision is located in cell 1000 . The program is located in loop 7.

## USING THE B REGISTER

Assume cell 3170 contains 01279420019.

Control continues in sequence to cell 1001.

The B Register is one of the most valuable tools available to the programmer. Use of the commands for the $B$ Register is as varied as the problems in the business world. The use of the commands is shown below. For a more refined use of the B Register, refer to the discussions of various techniques on the following pages.

PROBLEM: A manufacturing concern has an hourly payroll of 1000 employees. A daily computation of hours and earnings is required by employee number. Daily computations . are accumulated for the weekly payroll.

TO FIND: Accumulate hours and amount by employee number. Current daily totals are readily available if required. Totals are accumulated for weekly payroll processing.

ASSUME: Employee numbers range from 0000 through 0999. In the cell corresponding to the employee number is the current day's record for that employee. That is, in cell 0000 will be found the following information for employee 0000: his daily hours worked, and his wage rate. This information is stored in the following manner: xxx (hours), yyy (rate), 0000.

The accumulated hours and pay for each employee will be stored in cells 1000 through 1999, with the total for employee 0000 located in cell 1000 , that of employee 0001 in cell 1001, etc. This information is stored in the following manner: xxxx (hours), yyyyyy (amount of pay).

## SCALING

Scaling is an important part of a program. It is a problem for the programmer only, not the computer. The computer will always handle the data as ten digit numbers. The programmer, then, has the problem of keeping track of the movement of the decimal point.

In addition and substraction, scaling must locate the digits in a number so that the decimal points are in line. For example, 52.9 plus 5.32 is written

$$
\begin{aligned}
& 52.9 \\
&+\frac{5.32}{58.22} \text { and not } \quad \\
&+\frac{52.9}{10.61} \text { or } 106.1
\end{aligned}
$$

No further scaling is necessary for addition or subtraction.

However, multiplication and division change the position of the decimal point. In multiplication, when two 10 digit numbers are multiplied, the product is a 20 digit number in the A Register and the R Register. In division, the dividend is a 20 digit number, the divisor is a 10 digit number, and the quotient is a 10 digit number appearing in the A Register.

The following rule will be helpful to the programmer:
(1) In multiplication, the number of places to the right of the decimal point in the product is the sum of the number of decimal places to the right of the decimal point in the multiplicand and the multiplier.
(2) In division, the number of places to the right of the decimal point in the quotient is the number of places to the right of the decimal point in the dividend ( A and R ) minus the number of decimal places to the right of the decimal point in the divisor.

Examples:
(1) 00002250000 multiplied by 01000000000 is $00000225000 \quad 0000000000$
The number represented by 00002250000 is actually 2250 .
The number represented by 01000000000 is actually 10 .

Therefore, the number of decimal places to the right of the decimal point is:
Mutliplicand 3
Multiplier 8
Product (A and R) 11
The product, therefore, represented by
$00000225000 \quad 0000000000$ is actually $22,500$.
(2) 000001428120000000000 divided by 00000180000 is 07934000000 .
The number represented by 00000142812
0000000000 is actually 1428.12 .
The number represented by 00000180000 is actually 18.
Therefore, the number of decimal places to the right of the decimal point is:
Dividend 12
Divisor 4
Quotient (A) 8
The quotient, therefore, represented by 07934000000 is actually 79.34.

## COMMAND MODIFICATION AND CYCLING

In using a stored program machine such as DATATRON, it is often necessary to provide a means of modifying commands in order that a small program may be used repeatedly, but with different data each time the calculation is performed. To accomplish this effect, it is required that the instruction addresses which refer to the data be changed on each cycle.

The DATATRON provides two means for the programmer to accomplish command modification; i.e., B modification and programmed modification.

## B modification of commands:

Any command with a 1 in the first control digit (numerical minus sign) will have the contents of the B Register added to the instruction address of the command before
a it is executed. Example: Sum 500 sales stored in cells 0000-0499.

| Location |  | S ${ }^{\text {Control }}$ |  | Operation |  | Operand Address | Remarks |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Main | Loop |  |  | No. | Alphà |  |  |
|  |  |  |  |  |  |  |  |
| 0 | 7000 | 0 | 0000 |  | $S B$ | 2004 | SET BREGISTER TO O498 |
| 1 | 7001 | 0 | 0800 |  | CAD | 0499 | CLEAR AREGISTER AND AODLAST SALE |
| 2 | 7002 | 1 | 0000 |  | AD | [00007] | SUM SALES |
| 3 | 7003 | $\bigcirc$ | 0070 |  | $D B$ | 7002 | TALCY |
| 4 | 7004 | 0 | न000 |  | STOP | 0498 | COMPUTER WILL STOP WHEN <br> BREGISTER HAS COUNTEO DOWN |
| 5 | 5 |  |  |  |  |  | 499 TIMES |

In this case, the B Register serves two functions; i.e., automatic address modifier and tallying device, for which DB performs both functions.

## Programmed modification:

Any command may be inserted into the A Register. It appears to the DATATRON just as a number, and any
other number may be added or subtracted, thereby modifying the command. Usually, only the instruction address is modified. Example: 500 sales are stored in 0000-0499 which are to be summed.

The command in cell 7001 was modified on each cycle to serve as a tally device and refer to the next data item.

## USE OF THE QUICK ACCESS. LOOPS

## General:

The sole purpose of the quick access loops is to increase the speed of computer operation. Normally, all commands are executed from one of these loops, and, if possible, the data groups used in a section of the program are stored in any of the loops. Only under difficult situations should the program sequence be shifted to main storage where the speed of operation is ten times as lengthy. The blocking commands are provided to facilitate the use of the quick access loops.

## GENERAL RULES FOR USE OF THE QUICK ACCESS LOOPS

PROGRAMMING: Experience shows that the 7000 loop receives greatest use in programming because of the CUB command's dual function of blocking from main storage to the 7000 loop and then transferring control to the first command of the twenty words blocked. Of course, the program will operate at the same speed when using any of the three remaining loops. Normally programs are broken into segments of twenty commands or less such that discrete small groups of program steps are used in the loops as a unit. This does not mean that every twentieth step must be a CUB command but that a CUB
or CU or any other transfer command must appear at least once in every twenty commands as used in one loop. DATA STORAGE: For considerations of speed, it is desirable to store data and constants in the quick access loops along with the program. Generally, the program which has the least number of main memory instruction addresses will be the most rapid.
ADDRESSING: The accepted practice for designating quick access loop instruction addresses is to keep them within the ranges 4000-4019, 5000-5019, 6000-6019, 7000-7019.

## DATA EDITING

Usually in business problems, arithmetic computation is not complex. The general case is the making of logical decisions and the preparation of data in proper format for these decisions. The DATATRON provides five very convenient commands for this purpose, viz., CIRA, EX, SL, SR, UA.
CIRA. This command provides a means of "opening" a word any number of spaces and inserting additional digits. CIRA is really a shift left command that applies to the A Register only.

Example: Expand a six digit account number to eight digits, inserting 00 between the second and third digits.

| Location |  | $\begin{array}{c}\text { Control } \\ \text { Digits }\end{array}$ |  | Operation | Operand | Alphà | Address |
| ---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |$]$ Remarks

EXTRACT. This command is of great value in breaking down coded numbers (part numbers, account numbers, policy numbers, etc.) such that certain logical decisions requiring a particular type of processing may be made easily.

Example: Check a nine digit part number to determine whether the sixth digit (warehouse class code) is a 7 . If so, increase unit cost by $1 \%$.

| Location |  | S Digits |  | Operation |  | Operand Address | Remarks |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Main | Loop |  |  | NO | Alphá |  |  |
| 0 | 7000 | 0 | $10 \% 0$ |  | $C A D$ | 7014 | $A=0.0 \times \times \times \quad \times \times \times \times \times$ PRRT ${ }^{*}$ |
| 1 | 2001 | 0 | 0000 |  | $E X$ | 7011 | $A=0.000 x \text { 00 } 0000 \cdot \begin{gathered} \text { WAREE. } \\ \text { Cl. CRDE } \end{gathered}$ |
| 2 | 7002 | 0 | 0000 |  | 50 | 7010 | ) |
| 3 | $70{ }^{3}$ | 0 | 0800 |  | CNZ | 7009 | \} CHECK FOR " 7 " |

| 4 | 7014 | 0 | $0 \times \times \times$ | \|xx |  | $\times \times \times \times$ | PART NO. |

## TABLE LOOK-UP

In general, table look-up with the DATATRON is a simple and rapid machine process. Basically, the problem is this: a file exists in memory, and a particular item from the file is called for by each input item. If the file is lengthy, the search for the desired item may be timeconsuming unless it is efficiently programmed.
There are several methods of performing the search:

1. Comparing item by item, starting at the head of the table. This is the slowest but simplest method.
2. Comparing by starting at the middle of the table and continuously eliminating half the remaining possibilities. This is Binary Search and is usually fairly rapid. This technique should be used when the third method is not applicable.
3. The most used method, a particularly efficient one with the DATATRON, is this: construct the file in such a way that the location of each item is correlated to the input number itself. If this can be done, the DATATRON can use the input number (part number, employee number, etc.) to specify the address of the item in the table. Then the table entry can be called up directly, and no search for it need be performed.
In the simplest case, the input number can directly identify the memory location in the table. An example of this is the following.
PROBLEM: A bank has 3000 checking accounts. It keeps the current balance for each account in a file in
the DATATRON memory. Transactions are to be entered in groups as they are processed. Each account is assigned a number from 0000 to 2999 , and its current balance is kept in the corresponding memory location. Thus account number 1504 has its current balance recorded in location 1504.

100 transactions have been read into memory locations 3500-3599. Each is recorded in the following form:

$$
\pm \text { xxxxx0yyyy }
$$

where $\pm$ xxxxx $=$ transaction
yyyy = account number

The table look-up in this example was done without any searching, because the account number could be used to directly indicate the proper location of the proper current balance.

In most practical cases, the identifying number (account, employee, or part number) does not directly correspond to a memory address. The memory location corresponding to an input item must be computed or looked up as a separate operation before the table look-up can be carried out. In some cases, an arithmetic computation can convert the item into the appropriate address. In others, it is necessary to use a "dictionary" to find the memory location corresponding to an input item. In either case, the program operating time is somewhat increased. However, this method will still be much faster than an item-by-item search of the main file or a binary search.

| Location |  | $\begin{array}{\|l\|l} \hline \text { Control } \\ \hline \text { Digits } \end{array}$ |  | Operation |  | Operand Address | Remarks |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Main | Loop |  |  |  |  |  |  |
| 0 | 7000 |  | 9000 |  | CAD | 3500 | $A=x x x x x 0 y y y y$ |
| 1 | 7001 |  |  |  | ST | 7013 |  |
| 2 | 7002 |  |  |  | SB | 7013 | $B=$ y y y |
| 3 | 7003 |  |  |  | $5 R$ | 0005 | $A=00000 \times x \times x \times$ |
| 4 | 7004 | 1 | 0000 |  | $A D$ | 0000 | Add balance from file |
| 5 | 7005 | 1 | 0000 |  | $S T$ | 0000 | store new balance in file |
| 6 | 7006 |  |  |  | $C A D$ | 7000 |  |
| 7 | 7007 |  |  |  | $A D$ | 7012 |  |
| 8 | 7008 |  |  |  | $C C$ | 7011 | modify and Tally order |
| 9 | 7009 |  |  |  | STC | 7000 | in 7000 |
| 0 | 7010 |  |  |  | cu | 7000 | ) |
| 1 | 7011 |  |  |  | STOP | 0000 |  |
| 2 | 10/2 | 0 | 0010 |  | 00 | 0001 | Coustant To medify 7000 |

PROBLEM: A bank keeps current balances for checking accounts in a file in DATATRON memory. The account numbers vary from 00000 to 99999 , but only 1500 accounts exist. As before, the problem is to post transactions in the current balance file.

In this case, there is no correspondence between account number and memory location. For example, the current balance for account number 14708 may be in memory location 1695 , while 1696 contains the current balance for account number 35614. The file is maintained in account number sequence however. A dictionary must be provided which will relate the account number to the memory location where the current balance is stored.

The solution to this problem, as given below, is fairly complex. However, it shows the DATATRON performing a practical operation at high efficiency, and demonstrates the power of this table look-up technique.
SOLUTION: Table \#2 is composed of 1500 current balances stored in memory locations 1600-3099, and Table \#1 is composed of 1500 account numbers stored in locations 0100-1599. With each account number is stored the address of its balance (Table \#2) so that the entry has the following form.

$$
\begin{gathered}
\text { A } \\
\text { Table } \\
\text { \# } 1
\end{gathered}\left\{\begin{array}{l}
0 \text { dddd } \mathrm{xxxxx} \\
\text { Enfry }
\end{array}\right. \text { dddd = address of current balance in Table \#2. }
$$

The table of account numbers, Table \#1, is arranged in ascending sequence. A third table, Table \#3, is constructed, which consists of 100 BT4 commands referring
to Table \#1. The first two digits of the account number will correspond to a memory cell in Table \#3. The instruction address of the BT4 command in that cell will refer to Table \# 1. This table is stored in 0000-0099, and makes possible a very rapid look-up of the account number, in the following way.

1. An input account number is in 5000 , and the amount to be posted in 5001.
2. The first two digits of the account number call for the appropriate BT4 order from the Table \#3 in 0000-0099.
3. A BT4 command is executed, bringing a block of 20 account numbers from Table \#1 into Loop 4.
4. The 20 account numbers are searched by sequential comparison, and the desired account number is found. This is the only actual search necessary.
5. The address accompanying the matched account number is used to refer to the proper cell in the Table \#2.
6. The posting is performed, and the operation is complete.

## DESCRIPTION OF THE OPERATING CONTROLS ON THE DATATRON

1. CLEAR. When the CLEAR button is depressed, the A, R, B, C Registers, and all alarm indicators are set to zero and the DATATRON is placed in the execute state.
2. EXECUTE. When the DATATRON is in the execute phase, the EXECUTE light is on. When the START button is depressed, the command in the C Register will be executed. The DATATRON may be placed in the execute phase without depressing the CLEAR button by pressing the button directly beneath the EXECUTE light.
3. FETCH. When the DATATRON is in the fetch phase, the FETCH light is on. When the START button is depressed, the command whose storage address is specified by the contents of the Control Counter is inserted into the Order and Address Registers. The DATATRON may be placed in the fetch phase by pressing the button beneath the FETCH light.
4. CONTINUOUS-STEP.
a. CONTINUOUS. The DATATRON will automatically progress at high speed in sequence according to the program.
b. STEP. The DATATRON will proceed by single program steps in sequence according to the program. The START button must be pressed for each execute or fetch operation.
5. START. When the START button is depressed, the DATATRON will change from execute to fetch or vice versa. If the CONTINUOUS-STEP switch is set to STEP, program by program operation is performed; if set to CONTINUOUS, the DATATRON will proceed at high speed.
6. LOCK-NORMAL. During normal operations, this switch is in the NORMAL position. When it is in the LOCK position, the DATATRON is prevented from changing the phase, fetch or execute, of the cycle.
7. OVERFLOW. During the operation of the program in STEP or CONTINUOUS, if an overflow condition occurs and the command causing the overflow is not immediately followed by a Conditional Change command, the DATATRON will stop and the OVERFLOW indicator will be set. The indicator may be reset by pressing the RESET button beneath it.
8. SECTOR. When an internal timing error occurs, the DATATRON will stop, setting the SECTOR alarm. This indicator may be reset by pressing the RESET button beneath it.
9. F.C. When a forbidden combination (a binarycoded decimal digit greater than 9) is sensed, the DATATRON will stop. The sensing occurs on both fetch and execute cycles, and a forbidden combination may be detected in the A, R, B, C or D Registers.
10. CONTROL ALARM. When the command STOP (08) or an overflow not followed by a Conditional Change occurs, the CONTROL alarm is set. The
indicator may be reset by pressing the Reset button.
11. IDLE LIGHT. Whenever the DATATRON ceases high speed operation, the IDLE indicator is set.
12. ZERO. By pressing the ZERO button and simultaneously pressing any of the red buttons under the registers, a particular flip-flop of that register is reset.
13. All other buttons or switches on the Supervisory Control Panel are of no particular use to the operator; these are used primarily by the Customer Service Engineer.

## MANIPULATION OF THE CONTENTS OF THE REGISTERS

For each digit of any register, there are four flip-flops. Directly beneath each digit there are four red buttons. When any red button is pressed, the corresponding flipflop is ON. This provides a direct means of changing quantities in any register. When the DATATRON is being manually controlled, this is the only way of inserting desired quantities into any of the registers.

## OPERATING INSTRUCTIONS

All controls for operating the DATATRON are located on the Power Control Unit and the Supervisory Control Panel on the center of the DATATRON.

## 1. To turn the DATATRON on:

Figure 15. Power Control Unit
a. Turn on the MASTER CONTROL 115 V switch on the panel inside the left-hand door of the Power Control Cabinet.
b. Press the BLOWER ON button.
c. Press the FILAMENT ON button.
d. Press DRUM ON button.
e. Wait five minutes for tube temperatures to stabilize.
f. Press the MOTOR GEN(ERATOR) ON button. g. Press the DC FAIL RESET button.
h. Press the DC ON button.
i. This sequence must be followed.

## Figure 16. DATATRON Control Panel

2. To insert information (manual input): Storage of data, commands, or constants in the DATATRON is accomplished as follows:
a. Set CONTINUOUS-STEP switch to STEP and press the CLEAR button.
b. Insert the data item or command in the A Register by depressing the corresponding red buttons to form the proper binary-coded decimal representation of the digits desired.
c. Insert into the Order Register the STC (02) commans.
d. Insert into the Address Register the address of the storage location into which the number in the A Register is to be stored.
e. Press the START button. The STC command will be executed and the DATATRON will immediately stop.
3. To transfer control to a stored command:
a. Press the CLEAR button.
b. Set the CONTINUOUS-STEP switch to whichever phase is desired.
c. Insert the CU (20) command into the Order Register. Insert into the Address Register the location of the command to which control is to be transferred.
d. Press START button.
4. To operate the DATATRON continuously: Assuming that a command is in the C Register:
a. Set the CONTINUOUS-STEP switch to CONTINUOUS.
b. Press START button.
5. To operate the DATATRON step-by-step: Assuming that a command is in the C Register:
a. Set the CONTINUOUS-STEP switch to STEP.
b. Press START button. The command in the C Register will be executed.
c. Press START button. The command in the location specified by the Control Counter will be fetched into the Order and Instruction Address Registers. d. Press the START button. The command now in the Order and Instruction Address Registers will be executed. The START button must be depressed once for each fetch phase and once for each execute phase. As each execute phase is completed, the progress of the problem may be observed in the $\mathrm{A}, \mathrm{R}, \mathrm{B}, \mathrm{C}$ and D Registers.
6. To resume DATATRON operation at any selected point in the program: Assuming that the DATATRON has stopped (Overflow, the command STOP, forbidden combination, sector alarm, or a program imperfecion) :
a. Following the command STOP:

Press START button.
b. Following any other type of stop:

Execute Number 3.
7. To inspect a stored program in sequence: Occasionally it is necessary to inspect a series of data, commands, or constants stored on the drum.
a. Press the CLEAR button.
b. Insert into the Order Register CAD (64).
c. Place LOCK-NORMAL switch at LOCK.
d. Insert in the Address Register (C Register) the address of the location whose contents are to be displayed.
e. Press START button.
f. Return to Step d. until all necessary items have been examined.
8. To turn the DATATRON off: All controls to perform shut-down are located on the Power Control Unit.
a. Press DC OFF button.
b. Press MOTOR GEN(ERATOR) OFF button.
c. Press DRUM OFF button.
d. Press FILAMENT OFF button.
e. Press BLOWERS OFF button.
f. Turn off the MASTER CONTROL 115 V switch on the inside panel of the Power Control Unit. g. This sequence must be followed.
