## The high-performance goal

With the growing number of computer applications available to more and more users, the delivery of effective online service increasingly requires both large-capacity storage devices and fast access to the application and system data stored on those devices.

Increases in storage device capacity and in the number of stored data sets present a challenge to data processing professionals: management of the large DASD capacity, improvement of overall system performance, and enhancement of systems personnel productivity.

## Fast access to data

All of these needs—and more—are addressed by the new IBM 3880 Storage Control Model 13 which provides fast access to application and system data, with the potential to achieve dramatic increases in the DASD I/O throughput rate.

The 3880 Model 13 combines with 3380 Direct Access Storage units to provide a two-level, dynamically managed storage subsystem. Based on the IBM 3880 Model 3, the Model 13 employs two storage directors to control the 3380s. The difference, however, is that the directors for the Model 13 contain additional microcode to dynamically control a four- or eight-megabyte electronic cache. In this way, the Model 13 is designed to make most records available from the cache at electronic speeds, which reduces actuator contention and mechanical delays that occur with moving heads and rotating disks.

The cache storage directors share up to eight 3380 units—for a maximum of two full strings of 3380 DASD or 32 actuators per Model 13. In all, the Model 13 can control up to 20.16 billion bytes of direct access storage.

## Dynamic management is the key

Dynamic management of the cache contents effectively extends cache size. The high-performance characteristics of the 3880 Model 13 result from satisfying most processor data requests from the electronic cache. To accomplish this, the Model 13 reads and stores not only the specified disk record, but also records adjacent to it. These records are retained in the cache until replaced by more active records. Observations show that records are frequently read or written have a high probability of being located in close proximity in both space and time—“locality of reference.”

Thus, computer applications which exhibit a high probability of writes, as well as a high probability of “locality of reference” are likely to show significant performance improvements in average response time. Where response time appears, the more than a 50% improvement in throughput is the same result.

## Dynamic management is the key

Needs—and more—are met by the new IBM 3880 Direct Access Storage units which provide fast access to application data, with the potential for a dramatic increase in DASD I/O throughput rate.

The IBM 3880 Model 13 combines with the IBM 3880 Model 3, providing a two-level, dynamically managed storage subsystem. Based on the IBM 3880 Model 3, the Model 13 employs two storage directors to control the 3380s. The difference, however, is that the Model 13 contains additional microcode to dynamically control a four- or eight-megabyte electronic cache. In this way, the Model 13 is designed to make most records available from the cache at electronic speeds, which reduces contention and mechanical delays that occur with moving heads and rotating disks.

The cache storage directors share up to eight 3380 units—for a maximum of two full strings of 3380 DASD or 32 actuators per Model 13. In all, the Model 13 can control up to 20.16 billion bytes of direct access storage.

Dynamic management of the cache contents effectively extends cache size. The high-performance characteristics of the 3880 Model 13 result from satisfying most processor data requests from the electronic cache. To accomplish this, the Model 13 reads and stores not only the specified disk record, but also records adjacent to it. These records are retained in the cache until replaced by more active records. Observations show that records are frequently reused and that subsequent records read or written have a high probability of being located in close proximity, in both space and time—reflecting a high probability of a close "locality of reference."

Thus, computer applications which exhibit a high ratio of reads to writes, as well as a high incidence of "locality of reference," are likely to show substantial improvements in average disk response time. Where no other contention appears, there is a potential to more than double the DASD I/O throughput while maintaining the same response time.

## The value of systems performance

When measuring the value of computer systems in terms of terminal user satisfaction, two primary indicators emerge: fast response time and consistent response time.

The Model 13 can contribute to both by making the most active records available in the electronic cache when needed, thus reducing delays due to contention.

And since improved systems performance translates into improved service to end users—and the capability to service more of them—the Model 13 can help you get the most from your system.

## Enhancing DASD capacity

Considerable time and expertise are expended today to increase system performance. Many systems, for example, are configured with additional controllers and channels, with data distributed across multiple actuators. Though helping to reduce contention and average access times, these practices frequently result in reduced DASD capacity utilization. Because it can enhance the performance of the direct access storage subsystem, the 3880 Model 13 can allow you to utilize a larger percentage of the capacity you already have, while reducing the need for extra controllers and channels.

## An advance over fixed head storage

Fixed head disk storage is associated with the mechanical storage. The Model 13 eliminates the mechanical storage. Only the rotational delay, but the rotational delay. In addition, dynamic management of the cache offers t

over fixed head storage of changing the content of the cache to make the most active data the most readily available.

## Improving personnel productivity

Manual system tuning demands considerable effort by highly skilled systems personnel. Data set placement, for example, can result in improved performance. But the solution works only for a short time since patterns of data are constantly changing. For example, while more data is available at any given time, it is not necessarily used. DASD string activity may be high, but the actuators are not used.

Dynamic management of the cache offers t

and storage of changing  
of the cache to make  
ive data the most  
available.

### oving personnel ductivity

Annual system tuning demands a  
onsiderable effort by highly  
skilled systems personnel. Skillful  
data set placement, for example,  
can result in improved perform-  
ance. But the solution typically  
works only for a short duration,  
since patterns of data set activity  
are constantly changing. For  
example, while most data activity  
at any given time may be concen-  
trated on one or two actuators of a  
DASD string, during the next time  
period the highest level of data  
activity may shift to different  
actuators.

ition. Because  
performance  
s storage sub-  
Model 13 can  
ze a larger per-  
capacity you already  
ducing the need for  
bers and channels.

Dynamic management of the con-  
tents of the IBM 3880 Model 13  
cache can reduce the need for sys-  
tem tuning tasks such as load bal-  
ancing, and allow skilled systems  
personnel to devote their time to  
more productive tasks.

### Ease of installation

Installation of the IBM 3880  
Storage Control Model 13 requires  
no changes in job control lan-  
guage or application programs.

Supported by the MVS/System  
Product Release 3, the Model 13  
attaches to the IBM 30XX and 4341  
Model Group 2 processors via the  
three-megabyte-per-second,  
data streaming, block multiplexer  
channels of these systems.

### ance ixed head age

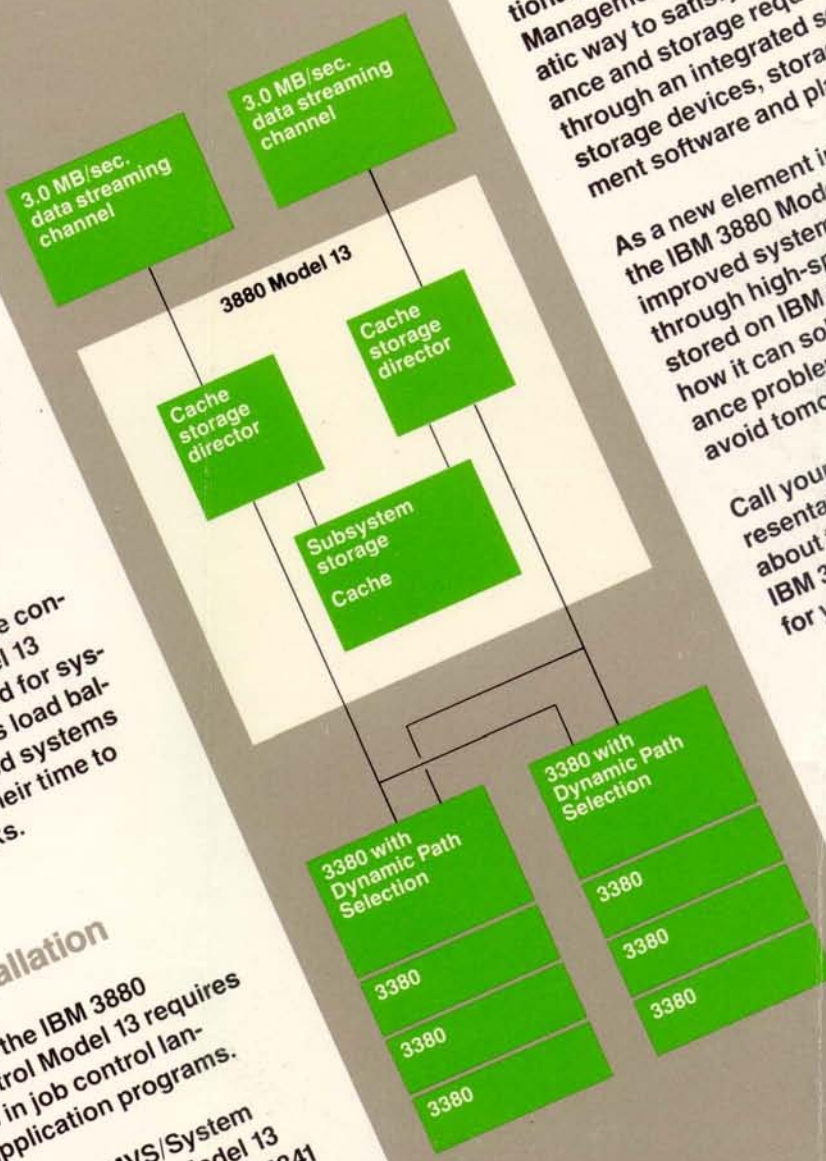

ed head disk storage is used to  
minate the mechanical seek time  
associated with moving head  
storage. The Model 13 reduces not  
only the mechanical delay as well,  
but the rotational delay as well.  
In addition, dynamic management  
of the cache offers the advantage

## The IBM 3880 Model 13... meeting storage needs in the '80s

The Model 13 is the latest evolu-  
tionary step in IBM's Total Storage  
Management approach—a system-  
atic way to satisfy user perform-  
ance and storage requirements  
through an integrated set of  
storage devices, storage manage-  
ment software and planning aids.

As a new element in this approach,  
the IBM 3880 Model 13 should offer  
improved systems performance  
through high-speed access to data  
stored on IBM 3380s. Think about  
how it can solve today's perform-  
ance problems while helping to  
avoid tomorrow's.

Call your IBM Data Processing rep-  
resentative soon for full particulars  
about the potential benefits of the  
IBM 3880 Storage Control Model 13  
for your installation.
